Package: elasdics (via r-universe)

August 23, 2024

Type Package

Title Elastic Analysis of Sparse, Dense and Irregular Curves

Version 1.1.3

Author Lisa Steyer <lisa.steyer@hu-berlin.de>

Maintainer Lisa Steyer <lisa.steyer@hu-berlin.de>

Description Provides functions to align curves and to compute mean curves based on the elastic distance defined in the square-root-velocity framework. For more details on this framework see Srivastava and Klassen (2016, <doi:10.1007/978-1-4939-4020-2>). For more theoretical details on our methods and algorithms see Steyer et al. (2023, <doi:10.1111/biom.13706>) and Steyer et al. (2023, <arXiv:2305.02075>).

Contents

`align_curves` *Align two curves measured at discrete points*

Description

Finds the optimal reparametrization of the second curve (stored in `data_curve2`) to the first one (stored in `data_curve1`) with respect to the elastic distance. Constructor function for class `aligned_curves`.

Usage

```
align_curves(data_curve1, data_curve2, closed = FALSE, eps = 0.01)
```

Arguments

`data_curve1`	`data.frame` with observed points in each row. Each variable is one coordinate direction. If there is a variable `t`, it is treated as the time parametrization, not as an additional coordinate.
`data_curve2`	same as `data_curve1`
`closed`	`TRUE` if the curves should be treated as closed.
`eps`	convergence tolerance

Value

an object of class `aligned_curves`, which is a `list` with entries

`data_curve1`	`data_curve1` with parametrization variable `t`
`data_curve2_aligned`	`data_curve2` with initial parametrization variable `t` and optimal parametrization `t_optim`
`elastic_dist`	elastic distance between curve1 and curve2
`closed`	`TRUE` if the curves should have been treated as closed.

Examples

```
#open curves
data_curve1 <- data.frame(x1 = c(1, 0.5, -1, -1), x2 = c(1, -0.5, -1, 1))
data_curve2 <- data.frame(x1 = c(0.1,0.7)*sin(1:6), x2 = cos(1:6))
aligned_curves <- align_curves(data_curve1, data_curve2)
plot(aligned_curves)

#different parametrization of the first curve
data_curve1$t <- 0:3/3
align_curves(data_curve1, data_curve2)

#closed curves
data_curve1 <- data.frame(x1 = sin(0:12/5), x2 = cos(0:12/5))
data_curve2 <- data.frame(x1 = c(1, 0.5, -1, -1), x2 = c(1, -0.5, -1, 1))
aligned_curves_closed <- align_curves(data_curve1, data_curve2, closed = TRUE)
plot(aligned_curves_closed, asp = 1)
```

`center_curve` *Centers curves for plotting*

Description

Centers curves for plotting

Usage

```
center_curve(data_curve)
```

Arguments

`data_curve`	curve data

Value

a `data.frame` with evaluations of the curve centered at the origin

`compute_elastic_mean` *Compute a elastic mean for a collection of curves*

Description

Computes a Fréchet mean for the curves stored in `data_curves`) with respect to the elastic distance. Constructor function for class `elastic_mean`.

Usage

```
compute_elastic_mean(
  data_curves,
  knots = seq(0, 1, len = 5),
  type = c("smooth", "polygon"),
  closed = FALSE,
  eps = 0.01,
  pen_factor = 100,
  max_iter = 50
)
```

Arguments

`data_curves`	list of `data.frames` with observed points in each row. Each variable is one coordinate direction. If there is a variable `t`, it is treated as the time parametrization, not as an additional coordinate.
`knots`	set of knots for the mean spline curve
`type`	if "smooth" linear srv-splines are used which results in a differentiable mean curve if "polygon" the mean will be piecewise linear.
`closed`	`TRUE` if the curves should be treated as closed.
`eps`	the algorithm stops if L2 norm of coefficients changes less
`pen_factor`	penalty factor forcing the mean to be closed
`max_iter`	maximal number of iterations

Value

an object of class `elastic_mean`, which is a `list` with entries

`type`	"smooth" if mean was modeled using linear srv-splines or "polygon" if constant srv-splines are used
`coefs`	spline coeffiecients
`knots`	spline knots
`data_curves`	list of `data.frames` with observed points in each row. First variable `t` gives the initial parametrization, second variable `t_optim` the optimal parametrization when the curve is aligned to the mean.
`closed`	`TRUE` if the mean is supposed to be a closed curve.

Examples

```
curve <- function(t){
  rbind(t*cos(13*t), t*sin(13*t))
}
set.seed(18)
data_curves <- lapply(1:4, function(i){
  m <- sample(10:15, 1)
  delta <- abs(rnorm(m, mean = 1, sd = 0.05))
  t <- cumsum(delta)/sum(delta)
  data.frame(t(curve(t)) + 0.07*t*matrix(cumsum(rnorm(2*length(delta))),
             ncol = 2))
})

#compute elastic means
knots <- seq(0,1, length = 11)
smooth_elastic_mean <- compute_elastic_mean(data_curves, knots = knots)
plot(smooth_elastic_mean)

knots <- seq(0,1, length = 15)
polygon_elastic_mean <- compute_elastic_mean(data_curves, knots = knots, type = "poly")
lines(get_evals(polygon_elastic_mean), col = "blue", lwd = 2)

#compute closed smooth mean, takes a little longer

knots <- seq(0,1, length = 11)
closed_elastic_mean <- compute_elastic_mean(data_curves, knots = knots, closed = TRUE)
plot(closed_elastic_mean)
```

`elasdics` *elasdics:* **el***astic* **a***nalysis of* **s***parse,* **d***ense and* **i***rregular* **c***urve***s**.

Description

The elasdics package provides functions to align observed curves and to compute elastic means for collections of curves.

Main functions

Align two observed curves: `align_curves`
Compute a mean for a set of observed curves: `compute_elastic_mean`

find_optimal_t *Optimal alignment to a smooth curve*

Description

Finds optimal alignment for a discrete open srv curve to a smooth curve

Usage

```
find_optimal_t(srv_curve, s, q, initial_t = s, eps = 10 * .Machine$double.eps)
```

Arguments

srv_curve	srv transformation of the smooth curve, needs to be vectorized
s	time points for q, first has to be 0, last has to be 1
q	square root velocity vectors, one less than time points in s
initial_t	starting value for the optimization algorithm
eps	convergence tolerance

Value

optimal time points for q, without first value 0 and last value 1, optimal time points have the distance of the observation to the srv_curve as an attribute

find_optimal_t_discrete *Finds optimal alignment for discrete open curves*

Description

Finds optimal aligned time points for srv curve q to srv curve p using coordinate wise optimization.

Usage

```
find_optimal_t_discrete(r, p, s, q, initial_t = s, eps = 10^-3)
```

Arguments

r	time points for p, first has to be 0, last has to be 1
p	square root velocity vectors, one less than time points in r
s	time points for q, first has to be 0, last has to be 1
q	square root velocity vectors, one less than time points in s
initial_t	starting value for the optimization algorithm
eps	convergence tolerance

Value

optimal time points for q, without first value 0 and last value 1 optimal time points have the distance of the observation to the srv_curve as an attribute

---

`find_optimal_t_discrete_closed`
Finds optimal alignment for discrete closed curves

Description

Finds optimal aligned time points for srv curve q to srv curve p using coordinate wise optimization.

Usage

```
find_optimal_t_discrete_closed(r, p, s, q, initial_t, eps = 10^-3)
```

Arguments

`r`	time points for p, first is last - 1
`p`	square root velocity vectors, one less than time points in r
`s`	time points for q, first is last - 1
`q`	square root velocity vectors, one less than time points in s
`initial_t`	starting value for the optimization algorithm
`eps`	convergence tolerance

Value

optimal time points for q, first is last -1

`fit_elastic_regression`
Compute a elastic mean for a collection of curves

Description

Computes a Fréchet mean for the curves stored in `data_curves` with respect to the elastic distance. Constructor function for class `elastic_reg_model`.

Usage

```
fit_elastic_regression(
  formula,
  data_curves,
  x_data,
  knots = seq(0, 1, 0.2),
  type = "smooth",
  closed = FALSE,
  max_iter = 10,
  eps = 0.001,
  pre_align = FALSE
)
```

Arguments

formula	an object of class "formula" of the form data_curves ~ ...".
data_curves	list of data.frames with observed points in each row. Each variable is one coordinate direction. If there is a variable t, it is treated as the time parametrization, not as an additional coordinate.
x_data	a data.frame with covariates.
knots	set of knots for the parameter curves of the regression model
type	if "smooth" linear srv-splines are used which results in a differentiable mean curve if "polygon" the mean will be piecewise linear.
closed	TRUE if the curves should be treated as closed.
max_iter	maximal number of iterations
eps	the algorithm stops if L2 norm of coefficients changes less
pre_align	TRUE if curves should be pre aligned to the mean

Value

an object of class elastic_reg_model, which is a list with entries

type	"smooth" if linear srv-splines or "polygon" if constant srv-splines were used
coefs	spline coeffiecients
knots	spline knots
data_curves	list of data.frames with observed points in each row. First variable t gives the initial parametrization, second variable t_optim the optimal parametrization when the curve is aligned to the model prediction.
closed	TRUE if the regression model fitted closed curves.

Examples

```
curve <- function(x_1, x_2, t){
  rbind(2*t*cos(6*t) - x_1*t , x_2*t*sin(6*t))
}
set.seed(18)
```

```
x_data <- data.frame(x_1 = runif(10,-1,1), x_2 = runif(10,-1,1))
data_curves <- apply(x_data, 1, function(x){
  m <- sample(10:15, 1)
  delta <- abs(rnorm(m, mean = 1, sd = 0.05))
  t <- cumsum(delta)/sum(delta)
  data.frame(t(curve((x[1] + 1), (x[2] + 2), t))
   + 0.07*t*matrix(cumsum(rnorm(2*length(delta))), ncol = 2))
})
reg_model <- fit_elastic_regression(data_curves ~ x_1 + x_2,
                                    data_curves = data_curves, x_data = x_data)
plot(reg_model)
```

`fit_mean` *Fitting function for open curves*

Description

Fits an elastic mean for open curves. Is usually called from `compute_elastic_mean`.

Usage

```
fit_mean(srv_data_curves, knots, max_iter, type, eps)
```

Arguments

`srv_data_curves`	list of `data.frames` with srv vectors in each row. Usually a result of a call to `get_srv_from_points`
`knots`	set of knots for the mean spline curve
`max_iter`	maximal number of iterations
`type`	if "smooth" linear srv-splines are used which results in a differentiable mean curve if "polygon" the mean will be piecewise linear.
`eps`	the algorithm stops if L2 norm of coefficients changes less

Value

a `list` with entries

`type`	"smooth" or "polygon"
`coefs`	`coefs` srv spline coefficients of the estimated mean
`knots`	spline knots
`t_optims`	optimal parametrization

`fit_mean_closed` *Fitting function for open curves*

Description

Fits an elastic mean for open curves. Is usually called from `compute_elastic_mean`.

Usage

```
fit_mean_closed(srv_data_curves, knots, max_iter, type, eps, pen_factor)
```

Arguments

`srv_data_curves`	list of `data.frames` with srv vectors in each row. Usually a result of a call to `get_srv_from_points`
`knots`	set of knots for the mean spline curve
`max_iter`	maximal number of iterations
`type`	if "smooth" linear srv-splines are used which results in a differentiable mean curve
`eps`	the algorithm stops if L2 norm of coefficients changes less
`pen_factor`	penalty factor forcing the mean to be closed if "polygon" the mean will be piecewise linear.

Value

a `list` with entries

`type`	"smooth" or "polygon"
`coefs`	`coefs` srv spline coefficients of the estimated mean
`knots`	spline knots
`t_optims`	optimal parametrization
`shift_idxs`	index of the starting point of the closed curve after alignment

get_evals *Evaluate a curve on a grid*

Description

Evaluate a curve on a grid

Usage

```
get_evals(curve, t_grid = NULL, ...)

## S3 method for class 'data.frame'
get_evals(curve, t_grid = NULL, ...)

## S3 method for class 'elastic_mean'
get_evals(curve, t_grid = NULL, centering = TRUE, ...)
```

Arguments

curve	a one parameter function which is to be evaluated on a grid
t_grid	the curve is evaluated at the values in t_grid, first value needs to be 0, last value needs to be 1. If t_grid = NULL, a default regular grid with grid length 0.01 is chosen
...	other arguments
centering	TRUE if curves shall be centered

Value

a `data.frame` with evaluations of the curve at the values in `t_grid` in its rows.

Examples

```
curve <- function(t){c(t*sin(10*t), t*cos(10*t))}
plot(get_evals(curve), type = "b")
```

get_srv_from_points *Helper functions for curve data measured at discrete points*

Description

Compute the square-root-velocity transformation or the parametrization with respect to arc length for a curve observed at discrete points.

Usage

```
get_srv_from_points(data_curve)

get_points_from_srv(srv_data)

get_arc_length_param(data_curve)
```

Arguments

data_curve	A data.frame with observed points on a curve. Each row is one point, each variable one coordinate direction. If there is a variable t, it is treated as the time parametrization, not as an additional coordinate.
srv_data	A data.frame with first column t corresponding to the parametrization and square-root-velocity vectors in the remaining columns.

Value

get_srv_from_points returns a data.frame with first column t corresponding to the parametrization and square-root-velocity vectors in the remaining columns. If no parametrization is given, the curve will be parametrized with respect to arc length. This parametrization will be computed by a call to get_arc_length_param as well.

Functions

- get_srv_from_points(): Compute square-root-velocity transformation for curve data measured at discrete points. The inverse transformation can be computed with get_points_from_s
- get_points_from_srv(): The inverse transformation to get_srv_from_points. Transforms square-root-velocity data to points representing a curve (with no parametrization).
- get_arc_length_param(): Compute arc length parametrization.

Examples

```
data_curve1 <- data.frame(x1 = 1:6*sin(1:6), x2 = cos(1:6))
get_arc_length_param(data_curve1) #same parametrization as in
get_srv_from_points(data_curve1)

data_curve2 <- data.frame(t = seq(0,1, length = 6), data_curve1)
plot(data_curve2[,2:3], type = "l", xlim = c(-6, 2), ylim = c(-2, 1))
srv_data <- get_srv_from_points(data_curve2)
#back transformed curve starts at (0,0)
lines(get_points_from_srv(srv_data), col = "red")
```

`optimise_one_coord_analytic` *Does optimization in one parameter direction*

Description

Does optimization in one parameter direction

Usage

```
optimise_one_coord_analytic(t, i, r, p, s, q)
```

Arguments

t	current time points, first has to be 0, last has to be 1
i	index of t that should be updated
r	time points for p, first has to be 0, last has to be 1
p	square root velocity vectors, one less than time points in r
s	time points for q, first has to be 0, last has to be 1
q	square root velocity vectors, one less than time points in s

Value

optimal time points for q with respect to optimization only in the i-th coordinate direction

`optimise_one_coord_analytic_closed` *Does optimization in one parameter direction*

Description

Does optimization in one parameter direction

Usage

```
optimise_one_coord_analytic_closed(t, i, r, p, s, q)
```

Arguments

t	current time points, first has to be 0, last has to be 1
i	index of t that should be updated
r	time points for p, first is last - 1
p	square root velocity vectors, one less than time points in r
s	time points for q, first is last - 1
q	square root velocity vectors, one less than time points in s

Value

optimal time points for q with respect to optimization only in the i-th coordinate direction

---

`plot.aligned_curves` *Plot method for aligned curves*

Description

Plots objects of class `aligned_curves`. Points of same color correspond after the second curve is optimally aligned to the first curve.

Usage

```
## S3 method for class 'aligned_curves'
plot(x, points_col = rainbow, ...)
```

Arguments

`x`	object of class `aligned_curves`, usually a result of a call to `align_curves`
`points_col`	which color palette is used for points on the curves, default is rainbow, see `rainbow` for further options.
`...`	further plotting parameters.

Value

No value

See Also

For examples see documentation of `align_curves`.

`plot.elastic_mean` *Plot method for planar elastic mean curves*

Description

Plots objects of class `elastic_mean`.

Usage

```
## S3 method for class 'elastic_mean'
plot(x, asp = 1, col = "red", ...)
```

Arguments

x	object of class elastic_mean, usually a result of a call to compute_elastic_mean
asp	numeric, giving the aspect ratio of the two coordinates, see plot.window for details.
col	color of the mean curve.
...	further plotting parameters.

Value

No value

See Also

For examples see documentation of compute_elastic_mean.

---

plot.elastic_reg_model

Plot method for planar elastic regression models

Description

Plots objects of class elastic_reg_model.

Usage

```
## S3 method for class 'elastic_reg_model'
plot(x, asp = 1, col = "red", ...)
```

Arguments

x	object of class elastic_reg_model, usually a result of a call to fit_elastic_regression
asp	numeric, giving the aspect ratio of the two coordinates, see plot.window for details.
col	color of the predicted curves.
...	further plotting parameters.

Value

No value

See Also

For examples see documentation of fit_elastic_regression.

predict.elastic_reg_model

Predict method for elastic regression models

Description

predicted curves for elastic regression model objects.

Usage

```
## S3 method for class 'elastic_reg_model'
predict(object, newdata = NULL, t_grid = seq(0, 1, 0.01), ...)
```

Arguments

object	object of class elastic_reg_model, usually a result of a call to fit_elastic_regression
newdata	an optional data.frame in which to look for variables with which to predict. If not given, the fitted values are used.
t_grid	grid on which the predicted curves are evaluated.
...	further arguments passed to or from other methods.

Value

a list of data.frames with predicted curves

See Also

For examples see documentation of fit_elastic_regression.

project_curve_on_closed

Close open curve via projection on derivative level.

Description

Close open curve via projection on derivative level.

Usage

```
project_curve_on_closed(data_curve)
```

Arguments

data_curve	data.frame with values of the curve.

Value

a `data.frame` with closed curve.

`srvf_to_curve` *Re-transform srv curve back to curve*

Description

Re-transform srv curve back to curve

Usage

```
srvf_to_curve(t, srv_curve)
```

Arguments

`t`	time points at which the resulting curve shall be evaluated.
`srv_curve`	srv curve as a function of one parameter, needs to be vectorized.

Value

a `matrix` with curve evaluations at time points t in its columns, rows correspond to coordinate directions

Index
